Erdős-Szekeres-type theorems for segments
and non-crossing convex sets

Abstract

A family $\mathcal{F}$ of convex sets is said to be in \textit{convex position}, if none of its members is contained in the convex hull of the others. It is proved that there is a function $N(n)$ with the following property. If $\mathcal{F}$ is a family of at least $N(n)$ plane convex sets with non-empty interiors, such that any two members of $\mathcal{F}$ have at most two boundary points in common and any three are in convex position, then $\mathcal{F}$ has $n$ members in convex position. This result generalizes a theorem of T. Bisztriczky and G. Fejes Tóth [BF1]. The statement does not remain true, if two members of $\mathcal{F}$ may share four boundary points. This follows from the fact that there exist infinitely many straight-line segments such that any three are in convex position, but no four are. However, there is a function $M(n)$ such that every family of at least $M(n)$ segments, any four of which are in convex position, has $n$ members in convex position.

1 Introduction

Erdős and Szekeres [ES1], [ES2] proved that any set of more than \(\binom{2n-4}{n-2}\) points in general position in the plane contains $n$ points which are in convex position, i.e., they form the vertex set of a convex $n$-gon. T. Bisztriczky and G. Fejes Tóth [BF1], [BF2], [F] extended this result to families of convex sets.

Throughout this paper, by a \textit{family} $\mathcal{F} = \{B_1, \ldots, B_t\}$ we always mean a family of compact convex sets in the plane in \textit{general position}, i.e., no three of them have a common supporting line, and no two are tangent to each other. $B_i \in \mathcal{F}$ is said to be a \textit{vertex} of

*Supported by NSF grant CCR-94-24938 and PSC-CUNY Research Award 667339
†Supported by OTKA-T-020914, OTKA-F-2234, and the Margaret and Herman Sokol Postdoctoral Fellowship Award.
If $B_i$ is not contained in the convex hull of the union of the others, i.e., if bd$\text{conv}(\cup \mathcal{F})$, the boundary of the convex hull of the union of all members of $\mathcal{F}$, contains a piece of the boundary of $B_i$. $\mathcal{F}$ is said to be in convex position if every member $B_i, (i = 1, \ldots, t)$ of $\mathcal{F}$ is a vertex of $\mathcal{F}$. Evidently, any two members of $\mathcal{F}$ are in convex position.

T. Bisztriczky and G. Fejes Tóth proved that there exists a function $N(n)$ such that if $\mathcal{F}$ is a family of pairwise disjoint convex sets, $|\mathcal{F}| > N(n)$ and any three members of $\mathcal{F}$ are in convex position, then $\mathcal{F}$ has $n$ members in convex position. In [PT], we have shown that this is true with $N(n) < 16^n$.

The aim of this paper is to extend the above result to families of not necessarily disjoint sets. A compact convex set in the plane with non-empty interior is called a convex body. Two convex bodies are said to be non-crossing, if they have at most two boundary points in common.

**Theorem 1.** For every $n$, there exists an integer $N = N(n) > 0$ with the following property. Every family of at least $N$ pairwise non-crossing convex bodies in the plane such that any three of them are in convex position, has $n$ members in convex position.

Theorem 1 cannot be generalized to families of convex bodies whose boundaries may have four intersection points per pair. Indeed, this can be shown by replacing in the following theorem each segment by a very narrow ellipse.

**Theorem 2.** There is an infinite family of straight-line segments in the plane such that any three of them are in convex position but no four are.

However, the next result shows that an analogue of Theorem 1 is true for families of segments, assuming that any four of them are in convex position.

**Theorem 3.** For every $n$, there exists an integer $M = M(n) > 0$ with the following property. Every family of at least $M$ straight-line segments in the plane such that any four of them are in convex position, has $n$ members in convex position.

In fact, we conjecture that for any $k > 2$, there exist a constant $m_k$ and a function $M_k(n)$ with the following property. Every family of at least $M_k(n)$ convex bodies in the plane such that any two share at most $k$ boundary points and any $m_k$ are in convex position, has $n$ members in convex position.

## 2 Proof of Theorem 1

Since $\mathcal{F}$ is in general position, small perturbations of the bodies do not effect whether or not a subset of $\mathcal{F}$ is in convex position. Therefore, we can assume that the boundary every member of $\mathcal{F}$ is smooth and no three members of $\mathcal{F}$ share a common boundary point.
Let $\mathcal{F} = \{B_1, B_2, \ldots, B_N\}$ be a family of non-crossing convex bodies in the plane. By Ramsey’s theorem, $\mathcal{F}$ has $\log_4 N$ members which are either pairwise disjoint or pairwise intersecting. In the first case, it follows from the (improved version [PT]) of the Bisztriczky-Féjes Tóth theorem [BFI] that there are many (at least $\log_{16} \log_4 N$) members in convex position, which exceeds $n$ if $N$ is large enough. So we can assume that $\{B_1, B_2, \ldots, B_{N'}\}$ is a subfamily of pairwise intersecting bodies, $N' \geq \log_4 N$.

We classify the ordered triples $(B_i, B_j, B_k)$, $i < j < k$, as follows. Let $I = \text{bd}(B_i) \cap B_j$, $I' = \text{bd}(B_i) \cap B_k$. Go along $\text{bd}(B_i)$ in clockwise direction. Denote the starting point and the endpoint of $I$ (resp. of $I'$) by $s$ and $e$ (resp. $s'$ and $e'$). The type of the ordered triple $(B_i, B_j, B_k)$, $i < j < k$, is determined by the clockwise order of $s, s', e, e'$ along $\text{bd}(B_i)$, and some other conditions, in the following way.

By Ramsey's theorem, if $N$ is large enough, then there is an arbitrarily large subfamily $\{B_1, B_2, \ldots, B_f\}$, all of whose ordered triples are of the same type. An easy case analysis shows that there are no four bodies such that all of their ordered triples are of type 1b, and no five such that all of their triples are of type 1c. By symmetry, we do not have to treat types 2a and 2b separately: it is enough to consider, say, type 2a. So, we are left with four cases according to the type of the ordered triples of $\{B_1, \ldots, B_f\}$.

**Case 1. All triples are of type 1a (see Fig. 2).**

Considering the triples $(B_1, B_i, B_{i+1})$, we can conclude that the intervals $I_i = bd(B_i) \cap B_i$ are pairwise disjoint and $I_2, I_3, \ldots, I_f$ follow each other on $bd(B_1)$ in, say, clockwise order. Since $B_i$ and $B_j$ ($1 < i, j \leq f$) intersect each other inside $B_1$, they do not intersect each other outside $B_1$. Let $x$ be the starting point of $I_2$. We can assume that $x$ is the leftmost point of $bd(B_1)$.

Let $y$ be the rightmost point of $bd(B_1)$. There is an $f'$ such that $I_2, I_3, \ldots, I_{f'}$ are on the arc $xy$ and $I_{f'+2}, I_{f'+3}, \ldots, I_f$ are on the arc $yx$. By symmetry, we can assume that $f' \geq f/2 - 2$. Let $l_x$ (resp. $l_y$) be the vertical supporting line of $B_1$ at $x$ (resp. $y$). There is a $g$ such that $B_2, B_3, \ldots, B_g$ do not intersect $l_x$ and $B_{g+2}, B_{g+3}, \ldots, B_f$ do not intersect $l_x$. Again, by symmetry, we can assume that $g \geq f'/2 - 2 \geq f/4 - 3$.

**Claim 1.** (i) $B_1$ is a vertex of $G = \{B_1, B_2, \ldots, B_g\}$.
(ii) $B_g$ is a vertex of $G$.
(iii) $G$ is in convex position.

**Proof.** (i) Since $l_y$ is a supporting line of $B_1$ and each $B_i$, $(2 \leq i \leq g)$ is to the left of it, we have that $y \in bd \left( \text{conv} \bigcup_{i=1}^g B_i \right)$ and $B_1$ is a vertex of $G$.

Since the bodies $B_2, B_3, \ldots, B_g$ do not intersect each other outside $B_1$, for any $1 < i < j < k \leq g$, $B_i, B_j$ and $B_k$ appear on $bd \left( \bigcup_{i=1}^g B_i \right)$ in this clockwise order. So, if $B_i, B_j, B_k$ each appears on the convex hull of $B_1, B_2, \ldots, B_g$, they appear in the same order.

(ii) Suppose that $B_g$ is not a vertex of $G$. Let $c = \max \{ i \mid B_i$ is a vertex of $G \}$. Then $B_g \subset \text{conv}(B_1 \cup B_c)$, a contradiction.
(iii) We show that for any fixed $1 < i < g$, $B_i$ is a vertex of $\mathcal{G}$. Suppose on the contrary that $B_i$ is not a vertex of $\mathcal{G}$. Let

$$c = \max\{ j < i \mid B_j \text{ is a vertex of } \mathcal{G}\}, \quad d = \min\{ j > i \mid B_j \text{ is a vertex of } \mathcal{G}\}.$$ 

Since $B_1$ and $B_g$ are both vertices of $\mathcal{G}$, $c$ and $d$ are well defined. Then $B_i \subset \text{conv}(B_c \cup B_d)$, a contradiction.

If we choose $N$ large enough, $g$ can be arbitrarily large, therefore in Case 1 we are done.

\[\Box\]

\[\text{Fig. 2.}\]

**Case 2.** All triples are of type 2a (see Fig. 2).

Let $s_i$ and $e_i$ denote the starting point resp. endpoint of $I_i = \text{bd}(B_i) \cap B_i$, in clockwise order. Considering the triples $(B_1, B_i, B_{i+1})$ and $(B_1, B_2, B_i)$, it is easy to deduce that the (clockwise) order of the points $s_i$ and $e_i$ ($i = 2, \ldots, f$) along $\text{bd}(B_1)$ is $s_2, s_3, \ldots, s_f, e_2, e_3, \ldots, e_f$, and $\text{bd}(\bigcup_{i=1}^f B_i)$ is composed of arcs belonging to $\text{bd}(B_1), \text{bd}(B_2), \ldots, \text{bd}(B_f)$ in this order. Therefore, those members of $\{B_1, B_2, \ldots, B_f\}$ which contribute to the boundary of $\text{conv} \bigcup_{i=1}^f B_i$, appear along this boundary in their original order.

**Claim 2.** (i) $B_1$ is a vertex of $\mathcal{G} = \{B_1, B_2, \ldots, B_f\}$.

(ii) $B_f$ is a vertex of $\mathcal{G}$.

(iii) $\mathcal{G}$ is in convex position.

**Proof.** (i) Suppose that $B_1$ is not a vertex of $\mathcal{G}$. Let
\[c = \min \{i \mid B_i \text{ is a vertex of } \mathcal{G}\}, \quad d = \max \{i \mid B_i \text{ is a vertex of } \mathcal{G}\}.
\]

Then \(B_1 \subseteq \text{conv}(B_c \cup B_d)\), a contradiction.

(ii) Suppose that \(B_f\) is not a vertex of \(\mathcal{G}\). Let \(c = \max \{i \mid B_i \text{ is a vertex of } \mathcal{G}\} \).

Then \(B_f \subseteq \text{conv}(B_1 \cup B_c)\), a contradiction.

(iii) The proof is exactly the same as the proof of (ii).

If we choose \(N\) large enough, \(f\) can be arbitrarily large, therefore in Case 2 we are done.

\[\square\]

**Case 3.** All triples are of type 3.

Let \(1 \leq i < j < f - 1\). Since \(B_{j+1} \not\in \text{conv}(B_i \cup B_j)\) and the ordered triple \((B_i, B_j, B_{j+1})\) is of type 3, \(bd(B_j)\) and \(bd(B_{j+1})\) intersect each other in two points outside \(B_i\). Thus, they do not intersect each other inside \(B_i\), so \(B_i \cap B_j \supseteq B_i \cap B_{j+1}\) (see Fig. 3).

Therefore, we can take an oriented line \(l\) with the following property. Let \(I_i = l \cap B_i\), with starting point \(s_i\) and endpoint \(e_i\). Then the order of the points \(s_i\) and \(e_i\) \((i = 1, \ldots, f)\) along \(l\) is \(s_1, s_2, \ldots, s_f, e_1, e_2, \ldots, e_f\).

We distinguish two further subtypes of triples \((B_i, B_j, B_k)\), \(1 \leq i < j < k \leq f\), in the following way. There are four uniquely determined points, \(p_1, q_1, p_2, q_2\), on \(bd(B_i \cup B_j \cup B_k)\), in this clockwise order, such that the piece of \(bd(B_i \cup B_j \cup B_k)\) which belongs to \(B_k\) (resp. \(B_i\)) is the arc \(p_1q_1\) (resp. \(p_2q_2\)).

We say that the triple \((B_i, B_j, B_k)\) is of type 3a (resp. 3b) if the arc \(q_1p_2\) (resp. \(p_2q_1\)) of \(bd(B_i \cup B_j \cup B_k)\) has a part which also belongs to \(bd(B_j)\). Since \((B_i, B_j, B_k)\) is in convex position, it is of type 3a or 3b (or both).
By Ramsey's theorem, there is a subfamily of size $g = \log_4 f$, all of whose ordered triples are of the same subtype.

For simplicity, denote this subfamily by $\{B_1, B_2, \ldots, B_g\}$. By symmetry, we can assume that all triples are of subtype 3a.

Claim 3. (i) $B_1$ is a vertex of $G = \{B_1, B_2, \ldots, B_g\}$.
(ii) $B_g$ is a vertex of $G$.
(iii) $G$ is in convex position.

Proof. (i) For any $1 < i \leq g$, let
\[ S_i = \{x \in \text{bd}(B_i) \mid B_1 \text{ has a supporting line at } x \text{ which avoids } B_i \}. \]
Every $S_i$ is an interval of $\text{bd}(B_i)$, and none of them contains $e_1$. Since any triple $(B_1, B_i, B_j)$ is in convex position and $S_i \cap S_j \neq \emptyset$, there exist a $y \in \cap_{i=2}^{g} S_i$ and a supporting line of $B_1$ at $y$, which avoids all other bodies.

(ii) The proof is analogous to the proof of (i).

(iii) Let $p$ be a point of $\text{bd}(B_1) \cap \text{bd}(\text{conv } \bigcup_{i=1}^{g} B_i)$ and let $q$ be a point of $\text{bd}(B_g) \cap \text{bd}(\text{conv } \bigcup_{i=1}^{g} B_i)$. We show that for any fixed $1 < i < g$, $B_i$ appears on the (clockwise) arc $pq$ of $\text{bd}(\text{conv } \bigcup_{i=1}^{g} B_i)$. Suppose, for a contradiction, that $B_i$ does not appear on the arc $pq$.

Let
\[ c = \max\{j < i \mid B_j \text{ appears on the arc } pq \text{ of } \text{bd}(\text{conv } \bigcup_{i=1}^{g} B_i)\}, \]
\[ d = \min\{j > i \mid B_j \text{ appears on the arc } pq \text{ of } \text{bd}(\text{conv } \bigcup_{i=1}^{g} B_i)\}. \]
Since $B_1$ and $B_g$ both appear on the arc $pq$, $c$ and $d$ are well defined. Then the triple $(B_c, B_i, B_d)$ is not of subtype 3a, a contradiction.

If we choose $N$ large enough, $g$ can be arbitrarily large, therefore in Case 3 we are done.

\[ \square \]

Case 4. All triples are of type 4.

Let $1 \leq i < j < k \leq m$. Since $B_j \not\subset \text{conv}(B_i \cup B_k)$ and the ordered triple $(B_i, B_j, B_k)$ is of type 4, $\text{bd}(B_j)$ and $\text{bd}(B_k)$ intersect each other in two points outside $B_i$. Therefore, the oriented triple $(B_k, B_j, B_i)$ is of type 1a, and we can proceed as in Case 1.

Thus, in all cases we can find $n$ bodies in convex position provided that $N$ is large enough. This completes the proof of Theorem 1. \[ \square \]

3 Proof of Theorem 2

For $i = 1, 2, \ldots$, let
\[ p_i = \left( -\sin \left( \frac{\pi}{2^i} \right), \ 1 - \cos \left( \frac{\pi}{2^i} \right) \right), \]
\[ a_i = \frac{1 - \cos(\frac{\pi}{2^i})}{\sin(\frac{\pi}{2^i})} \]

and, for some very large \( K \), let

\[ q_i = \left( \frac{K}{\sqrt{a_i}}, -K \cdot \sqrt{a_i} \right). \]

Finally, let \( S \) consist of all segments \( S_i = p_i q_i \) for \( i = 1, 2, \ldots \) (see Fig. 4).

Each segment \( S_i \) passes through the origin. One of its endpoints, \( p_i \), is on the circle \( x^2 + (y - 1)^2 = 1 \) so that \( p_{i+1} \) is the midpoint of the arc \( OP_i \). The other endpoint lies on the hyperbola \( xy = -K \). Since \( K \) is extremely large, the segments are very long.

Let \( i < j < l \). Notice that \( S_i \) intersects the line \( p_j p_l \). Therefore, \( p_i \) is not a vertex of \( \text{conv}(S_i, S_j, S_l) \). Since the hyperbola \( xy = -K \) is concave, \( q_i \) cannot be a vertex of \( \text{conv}(S_i, S_j, S_l) \) either. Thus, the vertices of \( \text{conv}(S_i, S_j, S_l) \) are \( p_i, p_j, q_i, q_l \), in counterclockwise order, which shows that any three segments are in convex position.

Now let \( i < j < k < l \). By the above observations, the vertices of \( \text{conv}(S_i, S_j, S_k, S_l) \) are \( p_i, p_j, q_i, q_l \). Thus, \( S_k \subset \text{conv}(S_i, S_j, S_l) \). \( \square \)

![Fig. 4.](image-url)
4 Proof of Theorem 3

Let $pq$ denote the closed straight-line segment connecting two points, $p$ and $q$. Let $S$ be a family of $M$ segments in the plane in general position, i.e., no two of them are parallel, no two of their endpoints have the same $x$-coordinate, and no three endpoints are collinear. By Ramsey’s theorem, $S$ has at least $\log_4 M$ members which are either pairwise disjoint or pairwise crossing. In the first case, we can apply the (improved version of the) Bisztriczky-Féjes Tóth theorem to conclude that $S$ has many (i.e., at least $\log_{16} \log_4 M$) members in convex position, which exceeds $n$, provided that $M$ is large enough.

So, we can assume that $S$ has $\log_4 M$ pairwise crossing members $S_1, S_2, \ldots$, and we can also suppose without loss of generality that they are listed in increasing order of slopes.

We classify the triples in $S$, as follows. Let $p_i$ and $q_i$ denote the left endpoint and the right endpoint of $S_i$, respectively. We say that two triples in $S'$, $(S_i, S_j, S_k)$ and $(S_{i'}, S_{j'}, S_{k'}) i < j < k, i' < j' < k'$, are of the same type if the following conditions are satisfied:

(i) the orientation of $p_i p_j p_k$ is the same as the orientation of $p_{i'} p_{j'} p_{k'}$;

(ii) the orientation of $q_i q_j q_k$ is the same as the orientation of $q_{i'} q_{j'} q_{k'}$;

(iii) for any $\alpha, \beta, \gamma, \delta \in \{i, j, k\}$, the half-lines $\overrightarrow{p_\alpha p_\beta}$ and $\overrightarrow{q_\alpha q_\beta}$ cross each other if and only if $\overrightarrow{p_\alpha p_\beta}$ and $\overrightarrow{q_\alpha q_\beta}$ do.

Note that it follows immediately from (iii) that

(iv) for any $\alpha, \beta, \gamma, \delta \in \{i, j, k\}$, $\overrightarrow{p_\alpha p_\beta}$ intersects the segment $q_\gamma q_\delta$ if and only if $\overrightarrow{p_\alpha p_\beta}$ intersects $q_\gamma q_\delta$. Similarly, $\overrightarrow{q_\alpha q_\beta}$ intersects $p_\gamma p_\delta$ if and only if $\overrightarrow{q_\alpha q_\beta}$ intersects $p_\gamma p_\delta$.

Applying Ramsey’s theorem to the triples of $S$, we obtain that there exists a subfamily $S' \subseteq S$ consisting of at least $f = f(M)$ segments (denoted by $S_1, S_2, \ldots, S_f$, for simplicity), all of whose triples $(S_i, S_j, S_k), i < j < k$, are of the same type. Here $f(M)$ is a suitable function which tends to infinity, as $M \to \infty$. In what follows, we will show that $S'$ is in convex position. This will complete the proof of the theorem, because if $M$ is sufficiently large, then $|S'| \geq f(M) \geq n$ holds.

Let $S_1, S_2, S_3 \in S'$. It cannot occur that the orientations of $p_1 p_2 p_3$ and $q_1 q_2 q_3$ are both clockwise; otherwise $S_2$ would be contained in the convex hull of $S_1 \cup S_3$, contradicting our assumption that any four segments are in convex position. Therefore, we have to distinguish two essentially different cases (up to symmetry about the $y$-axis).

**Case 1:** $p_1 p_2 p_3$ and $q_1 q_2 q_3$ are both counter-clockwise oriented.

**Subcase 1.1:** The half-line $\overrightarrow{p_2 p_3}$ intersects $q_2 q_3$, and $\overrightarrow{p_2 p_3}$ intersects $q_1 q_2$ (see Fig. 5).

Then $\overrightarrow{p_3 p_2}$ cannot intersect $q_3 q_4$. This implies that $(S_2, S_3, S_4)$ cannot have the same type as $(S_1, S_2, S_3)$, contradicting the definition of $S'$. Thus, this subcase cannot occur.
Subcase 1.1

Subcase 1.3

Fig. 5.

Subcase 1.2: $\overline{p_2p_3}$ does not intersect $q_2q_3$, and $\overline{p_2p_3}$ does not intersect $q_1q_2$ (see Fig. 6).

Every $p_i$, $1 \leq i \leq f$, is a vertex of the convex hull of $\cup S'$, so $S'$ is in convex position. Indeed, assume for contradiction that the line $p_ip_{i+1}$ is not a supporting line of $\text{conv}(\cup S')$. Then there is a $q_j$ on the right-hand side of $\overline{p_ip_{i+1}}$. If $j < i$, we find that $\overline{p_ip_{i+1}}$ intersects $q_jq_i$, contradicting the fact that $(S_j, S_i, S_{i+1})$ has the same type as $(S_1, S_2, S_3)$. If $j > i + 1$, then $\overline{p_{i+1}p_i}$ intersects $q_{i+1}q_i$, contradicting the fact that $(S_i, S_{i+1}, S_j)$ has the same type as $(S_1, S_2, S_3)$.

Subcases 1.2 and 2.2

Fig. 6.
By symmetries about the coordinate axes, we are left with the following subcase.

Subcase 1.3: \( \overrightarrow{p_2p_3} \) intersects \( q_2q_3 \), and \( \overrightarrow{q_2q_3} \) intersects \( p_2p_3 \) (see Fig. 5).

Now we have \( S_1 \subset \text{conv}(S_2 \cup S_3) \), a contradiction.

**Case 2:** \( p_1p_2p_3 \) is counter-clockwise and \( q_1q_2q_3 \) is clockwise oriented.

Subcase 2.1: \( \overrightarrow{p_2p_3} \) intersects \( q_1q_2 \) (see Fig. 4).

In this case, \( S_3 \subset \text{conv}(S_1 \cup S_2 \cup S_4) \), a contradiction.

By symmetry, we also have a contradiction if \( \overrightarrow{p_2p_3} \) intersects \( q_2q_3 \). Therefore, the only remaining case is the following.

Subcase 2.2: \( \overrightarrow{p_2p_3} \) does not intersect \( q_1q_2 \), and \( \overrightarrow{p_2p_3} \) does not intersect \( q_2q_3 \) (see Fig. 6).

It follows in exactly the same way as in Subcase 1.2 that every \( p_i \) (\( 1 \leq i \leq f \)) is a vertex of the convex hull of \( \cup S' \), hence \( S' \) is in convex position.

The above case analysis shows that we can always find \( f(M) \) segments in \( S \), which are in convex position. This completes the proof of Theorem 3, because \( f(M) \geq n \) if \( M \) is sufficiently large. □

5 Concluding Remarks

The proof of Theorem 3 can be modified to yield the following slightly more general result.

**Theorem 4.** For every \( n \), there exists an integer \( M' = M'(n) > 0 \) with the following property. Let \( \mathcal{F} \) be any family of at least \( M' \) convex sets in the plane such that

(i) the boundaries of any two intersect in at most four points,

(ii) no three have a point in common,

(iii) any four are in convex position.

Then \( \mathcal{F} \) has \( n \) members in convex position.

We conjecture that condition (ii) in Theorem 4 can be dropped.

In [KP], it was shown that every family of \( n \geq 3 \cdot \binom{l}{3} \cdot k \) convex sets in the plane has either \( k \) disjoint members or \( l \) members, no 3 of which have a point in common.

Combining this result with Theorems 1 and 4, we obtain

**Theorem 5.** For every \( k \geq 3 \) and for every \( n \), there exists \( M_k = M_k(n) > 0 \) with the following property. Let \( \mathcal{F} \) be any family of at least \( M \) convex sets in the plane such that

(i) the boundaries of any two intersect in at most four points,

(ii) no \( k \) have a point in common,

(iii) any four are in convex position.

Then \( \mathcal{F} \) has \( n \) members in convex position.
